

One Frontend Architecture Perspective

03.06.26

CONFIDENTIAL

One Frontend: Status quo & our proposed approach

Clarification of further steps and necessary alignment with key business stakeholder (Explore & Align, Decide, Execute)

Status quo

Key issues identified:

- Strategic direction not yet fully defined
 - No clearly agreed focus or target for the One Frontend FOA
 - Multiple perspectives and interpretations currently exist
- Alignment still evolving
 - Need for further refinement of the target direction
 - Shared understanding of the future state is still being established

Core challenge:

Further alignment and clarity will help to enable efficient progress.

Our proposed approach

First - "We present our understanding of the architecture, outline potential technical solutions, and gather stakeholder feedback to support decision-making."

Second - "Based on the agreed direction, we illustrate how a Proof of Concept (PoC) can be structured to demonstrate business value."

"Following alignment on the target approach (Option 1-3), architecture moves into execution with defined workstreams."

Option A) Linked Launchpad

Seamless navigation between applications while keeping systems independent

Linked Launchpad

Integration depth: low

You move to different app as part of the workflow and each app continue to run in their own infrastructure.

Pros:

- ✓ Fastest and most cost-efficient delivery approach
- ✓ Minimal impact on existing systems
- ✓ Facilitates system integration

Cons:

- Each connection may require a separate solution design
- Lack of a consistent user experience (UX)
- No streamlined or unified process integration

To do:

- 1) Identify all the workflow jump points
- 2) Identify the relevant context information to be shared for the jump

Option B) Embedded Workspace

Unified workspace experience with embedded applications inside one shared shell

Embedded Workspace

Integration depth: medium

You stay in one shell – apps run inside it, with one persistent navigation

Pros:

- ✓ One consistent shell (SSO) without leaving the environment
- ✓ Unified UI components across applications

Cons:

- No streamlined or end-to-end process integration
- Users may still need to switch between apps; the required level of automation needs to be defined

To do:

- 1) Extract frontend components and features from ELSA2Go
- 2) Establish organizational ownership & setup for UI components
- 3) Define integration patterns across applications
- 4) Assess required level of automation and revisit To-Dos from Slide 3 if needed

You need to click on the different "apps"

DCI Integration in ONE Frontend

To be completed/corrected...

[Click here - Back to slide 4](#)

Option C) Integrated Experience

Seamless end-to-end user journeys powered by API-driven integration

Integrated experience

Integration depth: high

Systems disappear—one seamless experience delivered through a single frontend , API-driven interface.

Pros:

- ✓ Lightweight UI enabling streamlined end-to-end process integration
- ✓ UI components decoupled from backend systems
- ✓ Reusable APIs across multiple frontends (e.g., DMS, external frontend)

Cons:

- DCI integration may not meet the end-of-2026 deadline

To do:

- 1) Define journey maps across key user processes
- 2) Identify required APIs and underlying data to support each journey
- 3) Assess required level of automation and revisit To-Dos from Slide 3 if needed

Architecture Proposed Approach

Driving alignment on the target approach and defining next steps for a one frontend strategy

Strategy Alignment

1

Before initiating a dedicated PoC, alignment with business stakeholders is required to define the target approach for the One Frontend strategy (Option 1-3).

Architecture execution

2

Following agreement on the target approach, architecture and business jointly move into execution, starting with a structured PoC and defined workstreams.

Key Architecture Activities

Foundation

- Perform due diligence (ELSA2Go, APIs, systems)
- Define design principles

Setup

- Establish organizational setup & ownership
- Define governance & guardrails

Architecture

- Define integration patterns
- Define API strategy

Experience design

- Define customer journeys
- Create wireframes (incl. DCI / ELSA integration)

Deep Dive - Foreign Frontends

...

Integration via Web Components

These are market specific frontends used for after sales service core process. The proposal is to build a web component in a fashion that the underlying API has the meta data describing frontend behavior which can be independently rendered by other frontends

How it works:

- Web Components encapsulate UI + logic
- Delivered via central platform (API + metadata)
- Can be integrated into any frontend (framework-independent)
- Behavior controlled via configuration

Deep Dive – Process Mining

Data-driven transparency to identify optimization and automation potential across business processes

Process Mining uncovers how processes are actually executed across systems by analyzing transaction and event data.

Example cross-system process flow:

"Actual process variants discovered in system data"

Key benefits of process mining :

- ✓ Creates end-to-end process transparency
- ✓ Identifies bottlenecks and process deviations
- ✓ Reveals automation and optimization potential

Process Mining Approach
